Abstract om du vil

I. INTRODUCTION

We can describe the evolution of many physical systems with the help of differential equations, but because of their complexity we are unable to solve these equations to find an analytical solution. Therefore we have to use numerical methods on computers in order to approximate the solution. Computers are limited in both their memory and accuracy so we have to be careful when both selecting the numerical method and how we implement it. In this report we are going to explore these issues by trying to solve the one-dimensional Poisson equation with Dirichlet boundary conditions, described in equation 3 in the theory section.

The example function we are going to use in our studies is described by the equation (1) and has an analytical solution (2) we can use to compare our results.

$$-\frac{d^2u}{dx^2} = f(x) = 100e^{-10x} \tag{1}$$

$$u(x) = 1 - (1 - e^{-10})x - e^{-10x}$$
 (2)

In order to solve equation (1) we end up with a set of linear equations described by a tridiagonal matrix multiplied with a vector (see the theory section for further explanation). Now there are many ways we can solve these equations, each with their own pros and cons. The methods we are going to explore is one where we solve for a general tridiagonal matrix, one where we specialize the algorithm to our tridiagonal matrix and lastly by using LU decomposition.

II. THEORY

A. Matrix formulation of the discrete one-dimensional Poisson equation

The one-dimensional Poisson equation with Dirichlet boundary conditions is given by equation 3.

$$-\frac{\mathrm{d}^2 u(x)}{\mathrm{d}x^2} = f(x), \quad x \in (0,1), \quad u(0) = u(1) = 0 \quad (3)$$

We definine the discretized approximation to u to be v_i at points $x_i = ih$ evenly spaced between $x_0 = 0$ and $x_{n+1} = 1$. The step length between the points is h = 1/(n+1). The boundary conditions from equation 3 then give $v_0 = v_{n+1} = 0$. An approximation to the second derivative of u, derived from the Taylor expansion, is

$$\frac{-v_{i-1}+2v_i-v_{i+1}}{h^2}=f_i \quad for i=1,2,...,n \qquad (4)$$

where $f_i = f(x_i)$. Written out for all *i*, equation 4 becomes

$$-v_0 + 2v_1 - v_2 = h^2 f_1$$

$$-v_1 + 2v_2 - v_3 = h^2 f_2$$
...
$$-v_{n-2} + 2v_{n-1} - v_n = h^2 f_{n-1}$$

$$-v_{n-1} + 2v_n - v_{n+1} = h^2 f_n$$

In general, this can be rearranged slightly so that

$$2v_1 - v_2 = h^2 f_1 + v_0$$

$$-v_1 + 2v_2 - v_3 = h^2 f_2$$
...
$$-v_{n-2} + 2v_{n-1} - v_n = h^2 f_{n-1}$$

$$-v_{n-1} + 2v_n = h^2 f_n + v_{n+1}$$

This system of equations can be written in matrix form as

$$\mathbf{A}\mathbf{v} = \tilde{\mathbf{b}},\tag{5}$$

explicitly

$$\begin{bmatrix} 2 & -1 & 0 & 0 & \dots & 0 \\ -1 & 2 & -1 & 0 & \dots & 0 \\ \vdots & & & & & & \\ \vdots & & & & & & \\ 0 & \dots & 0 & -1 & 2 & -1 \\ 0 & \dots & 0 & 0 & -1 & 2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ \vdots \\ v_{n-1} \\ v_n \end{bmatrix} = \begin{bmatrix} h^2 f_1 + v_0 \\ h^2 f_2 \\ \vdots \\ h^2 f_{n-1} \\ h^2 f_n + v_{n+1} \end{bmatrix}$$

With $v_0 = v_{n+1} = 0$, the right side reduces to $\tilde{b}_i = h^2 f_i$.

B. Solve tridiagonal matrix equation

In order to solve the tridiagonal matrix below we need to develop an algorithm. As mentioned in the exercise set [3] we first need to do a decomposition and forward substitution.

$$\mathbf{Av} = \begin{bmatrix} b_1 & c_1 & 0 & \dots & \dots & \dots \\ a_1 & b_2 & c_2 & \dots & \dots & \dots \\ & a_2 & b_3 & c_3 & \dots & \dots \\ & & & \ddots & \dots & \dots & \dots \\ & & & & a_{n-2} & b_{n-1} & c_{n-1} \\ & & & & & a_{n-1} & b_n \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ \dots \\ \vdots \\ v_n \end{bmatrix} = \begin{bmatrix} \tilde{b}_1 \\ \tilde{b}_2 \\ \dots \\ \vdots \\ \tilde{b}_n \end{bmatrix}.$$

Looking at the first matrix multiplication we get the following expression.

$$b_1v_1 + c_1v_2 = \tilde{b} \implies v_1 + \alpha_1v_2 = \rho_1, \quad \alpha_1 = \frac{c_1}{b_1} \wedge \rho_1 = \frac{\tilde{b}_1}{b_1}$$
(6)

Doing the second matrix multiplication we get

$$a_1v_1 + b_2v_2 + c_2v_3 = \tilde{b}_2 \tag{7}$$

If we multiply equation 6 by a_1 , and subtract it from equation 7 the resulting expression becomes

$$(b_{2} - \alpha_{1}a_{1})v_{2} + c_{2}v_{3} = \tilde{b}_{2} - \rho_{1}a_{1}$$

$$\implies v_{2} + \frac{c_{2}}{b_{2} - \alpha_{1}a_{1}}v_{3} = \frac{\tilde{b}_{2} - \rho_{1}a_{1}}{b_{2} - \alpha_{1}a_{1}}$$

$$\implies v_{2} + \alpha_{2}v_{3} = \rho_{2}$$
where $\alpha_{2} = \frac{c_{2}}{b_{2} - \alpha_{1}a_{1}} \wedge \rho_{2} = \frac{\tilde{b}_{2} - \rho_{1}a_{1}}{b_{2} - \alpha_{1}a_{1}}$

Noticing the pattern in ρ and α we can generalize the terms.

$$\alpha_i = \frac{c_i}{b_i - \alpha_{i-1}a_{i-1}}$$
 for $i = 2, 3, ..., n-1$ (8)

$$\rho_i = \frac{\tilde{b}_i - \rho_{i-1} a_{i-1}}{b_i - \alpha_{i-1} a_{i-1}} \text{ for } i = 2, 3, ..., n$$
 (9)

Inserting the terms into the matrix above, we get a much simpler set of equations.

$$\mathbf{Av} = \begin{bmatrix} 1 & \alpha_1 & 0 & \dots & \dots & \dots \\ 0 & 1 & \alpha_2 & \dots & \dots & \dots \\ 0 & 1 & \alpha_3 & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 1 & \alpha_{n-1} \\ & & & 0 & 1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ \dots \\ \vdots \\ v_n \end{bmatrix} = \begin{bmatrix} \rho_1 \\ \rho_2 \\ \dots \\ \vdots \\ \rho_n \end{bmatrix}.$$

Now the last step is to do a backward substitution. Starting with $v_n = \rho_n$ we can work our way backward, with the general expression

$$v_{i-1} = \rho_{i-1} - \alpha_{i-1}v_i$$
 for $i = n, n-1, ..., 2$ (10)

Now in this report we are going to consider a matrix with elements $b_n = 2$ and $a_n = c_n = -1$. We can insert this into equations (8) and (9) to get the expressions (11) and (12).

$$\alpha_i = \frac{-1}{2 + \alpha_{i-1}} \tag{11}$$

$$\rho_i = \frac{\tilde{b} + \rho_{i-1}}{2 + \alpha_{i-1}} \tag{12}$$
